

Barry Commoner Dead: Pioneering Environmental Scientist and Activist Dies at 95

Posted: 10/01/2012 8:37 am

Barry Commoner, a pioneering environmental scientist and activist, died Sunday at age 95.

Described in 1970 by *Time* magazine as the "Paul Revere of ecology," Commoner followed Rachel Carson as America's most prominent modern environmentalist. He viewed the environmental crisis as a symptom of a fundamentally flawed economic and social system. A biologist and research scientist, he argued that corporate greed, misguided government priorities, and the misuse of technology undermined "the finely sculptured fit between life and its surroundings."

Commoner insisted that scientists had an obligation to make scientific information accessible to the general public, so that citizens could participate in public debates that involved scientific questions. Citizens, he said, have a right to know the health hazards of the consumer products and technologies used in everyday life. Those were radical ideas in the 1950s and 1960s, when most Americans were still mesmerized by the cult of scientific expertise and such new technologies as cars, plastics, chemical sprays, and atomic energy.

Commoner linked environmental issues to a broader vision of social and economic justice. He called attention to the parallels among the environmental, civil rights, labor, and peace movements. He connected the environmental crisis to the problems of poverty, injustice, racism, public health, national security, and war.

Commoner first came to public attention in the late 1950s when he warned about the hazards of fallout caused by the atmospheric testing of nuclear weapons. He later used his scientific platform to raise awareness about the dangers posed by the petrochemical industry, nuclear power, and toxic substances such as dioxins. He was one of the first scientists to point out that although environmental hazards hurt everyone, they disproportionately hurt the poor and racial minorities because of the location of dangerous chemicals and because of the hazardous conditions in blue-collar workplaces. Commoner thus laid the groundwork for what later become known as the environmental justice movement.

Born in 1917, Commoner grew up in Brooklyn, New York, the child of Russian Jewish immigrants. He studied zoology at Columbia University and received a doctorate in biology from Harvard University in 1941. After serving in the Navy during World War II, Commoner was an associate editor for *Science Illustrated* and then became a professor at Washington University in St. Louis, Missouri, a position he held for thirty-four years.

There he founded, in 1966, the Center for the Biology of Natural Systems to promote research on ecological systems. He later moved the center to Queens College in New York.

While serving in the Navy, Commoner discovered the disturbing unintended consequences of technology. He was put in charge of a project to devise an apparatus to allow bombers to spray DDT on beachheads to kill insects that caused disease among soldiers. The military wanted to remove the insects before troops landed. Commoner's crew discovered that the DDT sprayed from bombers effectively eliminated hordes of flies on the beach, but also that more flies soon came to feast on the tons of fish that the DDT had also killed. This lesson became a central theme for Commoner throughout his career: humans cannot take action on one part of the ecosystem without triggering a reaction elsewhere.

After the war, many scientists, including Albert Einstein, alarmed by America's use of the atomic bomb on Japan in 1945, began to rethink their role in society. They questioned whether dropping the bomb had been necessary for the United States to win the war. They were shocked by the scale of the damage in terms of both immediate deaths and long-term human suffering. And they worried about the potential for a prolonged arms race between the United States and the Soviet Union, which, they feared, could end in a nuclear war in which all humanity would be the losers.

As Commoner **told** *Scientific American* in a 1997 interview:

The Atomic Energy Commission had at its command an army of highly skilled scientists. Although they knew how to design and build nuclear bombs, it somehow escaped their notice that rainfall washes suspended material out of the air, or that children drink milk and concentrate iodine in their growing thyroids. I believe that the main reason for the AEC's failure is less complex than a cover-up but equally devastating. The AEC scientists were so narrowly focused on arming the United States for nuclear war that they failed to perceive facts -- even widely known ones -- that were outside their limited field of vision.

Commoner and other scientists -- including chemist Linus Pauling (a professor at the California Institute of Technology and a Nobel Prize winner) -- believed they had a responsibility to sound the alarm about the potentially devastating effects of nuclear fallout. In 1956, when Adlai Stevenson ran for president as the Democratic Party nominee, he sought Commoner's advice and then called for the United States to take the lead in ending nuclear testing.

In 1958 Commoner and other scientists and activists formed the Committee for Nuclear Information with the goal of educating the public to understand how, in Commoner's words, "splitting a few pounds of atoms could turn something as mild as milk into a devastating global poison." They started a new publication, *Nuclear Information* (later renamed *Scientist and Citizen*), to discuss the responsibility of scientists to the larger society. They drafted a petition, signed by 11,021 scientists worldwide, urging that "an international agreement to stop the testing of nuclear bombs be made now." These activities created a groundswell of public opinion that eventually helped persuade President John F. Kennedy to propose the 1963 Nuclear Test Ban Treaty.

Commoner's early experience with DDT led him to espouse what scientists call the "precautionary principle" -- that new chemicals and technologies should not be introduced into society if there is reason to believe that they pose a significant public health risk. They should be approved only after it can be demonstrated that they are safe. Commoner warned about the risks to human health posed by detergents, pesticides, herbicides, radioisotopes, and smog. He argued that polluting products (such as detergents and synthetic textiles) should be replaced with natural products (such as soap, cotton, and wool). He alerted the public to the negative effects of nuclear power plants, toxic chemicals, and pollution on the economy, birth defects, and diseases like asthma.

In the 1970s Commoner spoke out against the view that overpopulation, particularly in the Third World, was responsible for the increasing depletion of the world's natural resources and the deepening ecological problems. The thesis was popularized by Paul Ehrlich (in his book *The Population Bomb*) and other scientists, but Commoner challenged those who echoed the ideas of the 19th-century British thinker Thomas Robert Malthus.

As Commoner argued, it is rich nations that consume a disproportionate share of the world's resources. And it was their systems of colonialism and imperialism that led to the exploitation of the Third World's natural resources for consumption in the wealthy nations, making the poor even poorer. Without the financial resources to improve their living conditions, people in developing countries relied more heavily upon increased birthrates as a form of social security than did people in wealthier nations.

As Commoner wrote, "The poor countries have high birthrates because they are extremely poor, and they are extremely poor because other countries are extremely rich." His solution to the population problem was to increase the standard of living of the world's poor, which would result in a voluntary reduction of fertility, as has occurred in the rich countries.

In *The Closing Circle* (1971), Commoner argued that our economy -- including corporations, government, and consumers -- needs to be in sync with what he called the "four laws of ecology":

- Everything is connected to everything else.
- Everything must go somewhere.
- Nature knows best.
- There is no such thing as a free lunch

The Closing Circle helped introduce the idea of *sustainability*, a notion that is now widely accepted but was controversial at the time. As Commoner pointed out, there is only one ecosphere for all living things. What affects one, affects all. He also noted that in nature there is no waste. We can't throw things away. Therefore, we need to design and manufacture products that do not upset the delicate balance between humans and nature. We need to utilize alternative forms of energy, such as wind, solar, and geothermal power. And we need to change our consumption habits accordingly -- to use fewer products with plastics (which are based on oil), aerosol cans (which harm the atmosphere), and industrial-grown food (which is produced with harmful chemicals).

In his best-selling book *The Poverty of Power* (1976), Commoner introduced what he called the "Three Es" -- the threat to environmental survival, the shortage of energy, and the problems (such as inequality and unemployment) of the economy--and explained their interconnectedness: Industries that use the most energy have the most negative impact on the environment. Our dependence on nonrenewable sources of energy inevitably leads to those resources becoming scarcer, raising the cost of energy and hurting the economy.

Commoner was neither a back-to-the-land utopian nor a Luddite opposed to modern industrial civilization. He did not place the burden of blame on the consumers who buy these products or the workers who produce them. He believed that big business and their political allies dominate society's decision making, often leading to misguided priorities, a theme that paralleled the ideas of economist John Kenneth Galbraith and, later, Ralph Nader.

Commoner believed that the corporate imperative for wasteful growth is the root cause of the environmental crisis and must be corralled by responsible public policies demand by a well-educated public. As he told *Scientific American*:

The environmental crisis arises from a fundamental fault: our systems of production -- in industry, agriculture, energy and transportation -- essential as they are, make people sick and die.

Commoner's proposals for addressing these problems reflect his lifetime of promoting a progressive agenda. He told *Scientific American*:

What is needed now is a transformation of the major systems of production more profound than even the sweeping post-World War II changes in production technology. Restoring environmental quality means substituting solar sources of energy for fossil and nuclear fuels; substituting electric motors for the internal-combustion engine; substituting organic farming for chemical agriculture; expanding the use of durable, renewable and recyclable materials -- metals, glass, wood, paper -- in place of the petrochemical products that have massively displaced them.

Commoner acknowledged some of the environmental movement's victories, including bans on DDT and on lead in gasoline. Commoner saw this as a evidence that society can prevent environmental hazards by changing the way we produce and consume. But in a 2007 interview with the *New York Times*, he **warned** that these measures did not go far enough.

Environmental pollution is an incurable disease. It can only be prevented. And prevention can only take place at the point of production. If you insist on using DDT, the only thing you can do is stop. The rest has really been sort of forgotten about.

Many Americans embraced Commoner's ideas about workplace hazards, nuclear power plants, and recycling. But he grew frustrated by the influence of corporate America over both political parties and by the failure of the mainstream environmental movement to join forces with other progressive movements to heed his warnings and challenge the basic tenets of the free-market system.

In 1979 Commoner helped form the Citizens Party, hoping it would gain influence similar to that of the Green Party in Europe. The next year Commoner ran as the party's presidential candidate. He got on the ballot in twenty-nine states but received less than one-third of 1 percent of the national vote. Like most third parties in the American system, the Citizens Party wound up being a minor fringe force. Commoner did not run again for office, but he advised Jesse Jackson's Democratic Party presidential campaigns in the 1980s.

In the 2007 interview with the *New York Times*, then-90-year-old Commoner remained the relentless radical:

I think that most of the 'greening' that we see so much of now has failed to look back on arguments such as my own -- that action has to be taken on what's produced and how it's produced. That's unfortunate, but I'm an eternal optimist, and I think eventually people will come around.

Peter Dreier is professor of politics and chair of the Urban & Environmental Policy Department at Occidental College. His book, [The 100 Greatest Americans of the 20th Century: A Social Justice Hall of Fame](#), was recently published by Nation Books. Barry Commoner is one of the people profiled in that book.
